Contracts and Functions

Function Deep Dive

Function Convention

```
function getASum (uint a, uint b) public pure override returns (uint) checkSize {}
```

Declaration

Function
Name

Inputs

Visibility

Mutability

Override
/Virtual

Output
Type

Custom
Modifiers

These are optional

Function Visibility

public Function is callable by anyone, including other contracts and itself.	private Function can only be executed within its contract. Cannot be inherited or externally called.
internal Function can only be called by its contract and the contracts which inherit the contract it lives in.	external Function will only ever be called by external users and contract, not by the contract itself internally. It is cheaper than public functions as it accesses calldata.

Function Mutability

pure

No state variable will be changed or read.

view

State variable will be read but not changed.

Combined with "external", the function is free!

Function inheritance - virtual / override

Interface Functions are automatically virtual

Private Functions cannot be inherited

In the case of **Multiple Inheritance**, with parents who have functions with the same name, child contract **MUST** override the function with the same name!

Custom Function Modifiers

```
pragma solidity ^0.5.0;

contract Owner {
    address owner;
    constructor() public {
        owner = msg.sender;
    }
    modifier onlyOwner {
        require(msg.sender == owner);
        _;
    }
    modifier costs(uint price) {
        if (msg.value >= price) {
            _;
        }
    }
}
```

Declare using the "**modifier**" keyword.
_ ; signals start of main function

Modifiers properties:

- Can be inherited
- Can take arguments
- Many in same function
- Can be overridden

Function Overloading

```
function sameName(int a){}
```

```
function sameName(int a, string b){}
```

```
function sameName(int a, int b){}
```

A function with multiple, different inputs but the same function name is an overloaded function.

Functions may be overload with:

- ❖ A different number of inputs
- ❖ Different types of inputs

Special Functions

Validation and Assertion

- `require(cond)`, `require(cond, error_msg)` is used to check inputs
- `revert()`, `revert(msg)` is used to abort execution given internal errors
- `assert(cond)` is used to prevent logical errors like integer overflow

```
function withdraw(uint256 amount) public {  
    require(balance[msg.sender] >= amount, "insufficient balance");  
    if (!msg.sender.send(amount)) {  
        revert("transfer failed");  
    }  
    balance[msg.sender] -= amount;  
}
```

Send, Transfer, Call - low level functions

receivingAddress.transfer(amount);

- Success - 2300 gas unit payment
- Failure - Revert

receivingAddress.send(amount);

- Success - 2300 gas unit payment
- Failure - Returns bool. Handled by initiating SC

(bool success, bytes memory data)= receivingAddress.call{gas: limit; value: wei}("");

- Can call specific function signature (ie. different payment methods)
- Empty function directly calls fallback or receive function
- Can specify gas limit or use all gas in calling contract. Enables complex operations
- Function params encoded with abi.encodeWithSignature
- **What happens when the called contract makes a call to the original calling contract?**

Fallback, Receive

`receive() external payable{}`

- First line of defense

`fallback() external payable{}`

- Second line of defense

- Does NOT contain the function keyword
- MUST be external and payable
- Worst case scenario: 2300 Gcallstipend
- Can be virtual overridden and contain modifiers

See it in action with Solidity Scripting

Globally Available Variables

Block, Transaction

Block properties

`blockhash(uint blockNumber)` returns (bytes32): hash of the given block when blocknumber is one of the 256 most recent blocks; otherwise returns zero

`block.basefee (uint)`: current block's base fee (EIP-3198 and EIP-1559)

`block.bloibasefee (uint)`: current block's blob base fee (EIP-7516 and EIP-4844)

`block.chainid (uint)`: current chain id

`block.coinbase (address payable)`: current block miner's address

`block.difficulty (uint)`: current block difficulty (EVM < Paris).

`block.gaslimit (uint)`: current block gaslimit

`block.number (uint)`: current block number

`block.prevrandao (uint)`: random number provided by the beacon chain (EVM \geq Paris)

`block.timestamp (uint)`: current block timestamp as seconds since unix epoch

Transaction Properties

tx.gasprice (uint): gas price of the transaction

tx.origin (address): sender of the transaction (full call chain)

msg.data (bytes calldata): complete calldata

msg.sender (address): sender of the message (current call)

msg.sig (bytes4): first four bytes of the calldata (i.e. function identifier)

msg.value (uint): number of wei sent with the message

tx.origin

User → Contract A → Contract B → Contract C

msg.sender

msg.sender

Delegatecall - A Special Call

```
contractB.delegatecall(abi.encodeWithSignature("myFunc()", inputs) );
```

tx.origin = msg.sender

```
contract A {
```

```
function delegate(){  
  contractB.delegatecall(  
    abi.encodeWithSig(  
      myFunc", inputs)  
    );  
};
```

```
Do stuff  
Some more stuff  
Setting a storage variable
```

```
}
```

```
contract B {
```

```
function myFunc(){
```

```
Do stuff  
Some more stuff  
Setting a storage variable
```

```
}
```

```
}
```

Smart Contract properties

Inheritance and Memory

Inheritance - sharing is caring

Single

Functions and state variables of parent goes to child

contract parent {}

contract child is parent {}

Multi-level

Chain of inheritance, all properties gets cumulatively passed down each generation

contract A {}

contract B is A {}

contract C is B {}

Hierarchical

A parent can have many children

contract parent {}

contract child1 is parent {}

contract child2 is parent {}

Multiple

Inherit from many different contracts

contract child is
parent1, parent2,
parent3 {}

Inheritance - Interfaces and Abstract Contracts

Interface

- ❖ Only used as templates
- ❖ No function implementation logic
- ❖ No constructors or state variables
- ❖ Only external functions, automatically virtual
- ❖ Cannot inherit

Abstract Contract

- ❖ Used as base for other contracts. is itself a contract
- ❖ Mix of implemented and unimplemented functions
- ❖ Can have constructor and state variable
- ❖ can inherit

```
interface InheritMe{  
    function getBalance(address _user) external view{}  
}
```

Interfaces - Birds of a feather, work together

Variable Scope in Smart Contracts

```
contract MyContract {
```

```
    int public a;
```

```
    mapping(address => int) ownerBalances;
```

- State variables are always stored onchain.
- They are inherited

```
    function checkBalance(address _owner) external view {
```

```
        int b = 5;
```

```
        return b + ownerBalances[_owner];
```

```
    }
```

```
}
```

- Local variables are in transient memory.
- They are not inherited

Memory Management in Smart Contracts

<h2>Memory</h2> <ul style="list-style-type: none">❖ Lasts for the length of a function call❖ Stored on EVM❖ Values are mutable❖ Most versatile	<h2>Calldata</h2> <ul style="list-style-type: none">❖ Extremely tiny❖ User/contract inputs❖ Immutable❖ Use as safe guard
<h2>Storage</h2> <ul style="list-style-type: none">❖ Permanent on chain storage❖ Extremely expensive!!❖ Can use push function❖ Use for state variables only	<h2>Stack</h2> <ul style="list-style-type: none">❖ Very small❖ Stores things for immediate execution❖ Gas Efficient❖ Extremely painful -> inline assembly

Upgradeable Contracts

Upgradable Proxy Architecture

Function Clashes

Function Signature

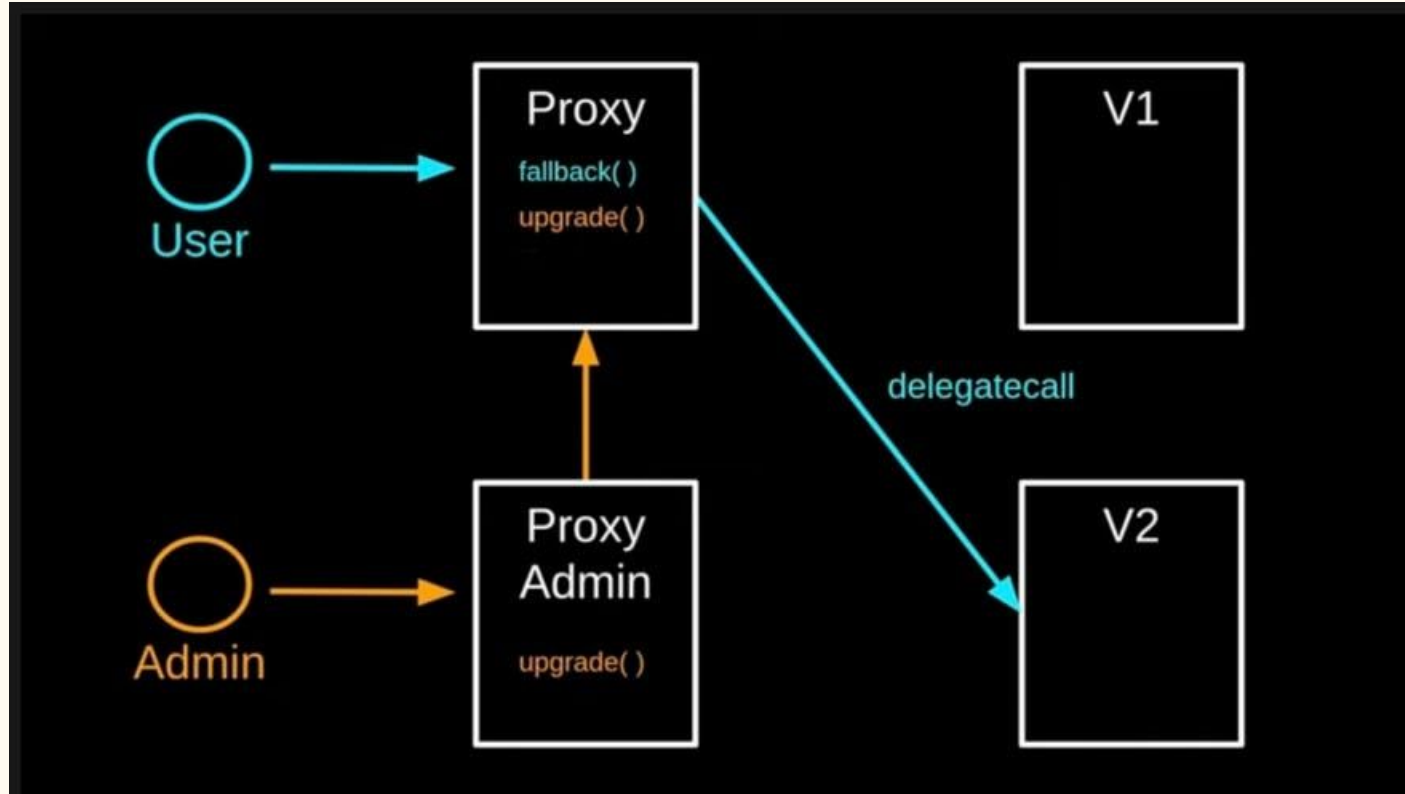

```
function transfer(address sender, uint256 amount) public {  
    // Some code here  
}
```

```
transfer(address,uint256)
```

Function Selector

```
bytes4(keccak256(bytes(function_signature)))
```

Transparent Proxy Model

Storage Collisions

```
bytes32 private constant implementationPosition = bytes32(uint256(
    keccak256('eip1967.proxy.implementation')) - 1
));
```

Always append state vars, not modify

UUPS Proxy Model - EIP 1822

Cost Comparison

	Transparent	UUPS
Proxy Deployment	740k + 480k ProxyAdmin	390k
Implementation Deployment	+ 0	+ 320k
Runtime Overhead	7.3k	4.9k

Solidity Events

Ethereum Accounting - Tries Revisited

Block, transaction, account state objects and Ethereum tries

Events - Transaction Record

- Security Audits
 - Traditional accounting - does the stored variable add up to all events?
- User Interface
 - Confirm a transaction has happened
 - Change the interface after confirmation
- Cryptographic checks
 - Bloom filters

Event - Declaration and Actualization

```
contract Transaction {  
    event makeATransfer(address indexed _from, address indexed _to, uint amount);  
  
    function payRent(address receiver, uint deposit) external {  
        require(msg.sender.balance >= msg.value);  
        emit makeATransfer(msg.sender, receiver, amount);  
    }  
}
```

Events - ABI representation

```
{  
  "returnValues": {  
    "_from": "0x1111...FFFFCCCC",  
    "_to": "0x50...sd5adb20",  
    "amount": "0x420042"  
  },  
  "raw": {  
    "data": "0x7f...91385",  
    "topics": ["0xfd4...b4ead7", "0x7f...1a91385", "0xf28...d21297" ]  
  }  
}
```
